Use Case

Target group: Commuting students, particularly those traveling to and from our location in Rotkreuz.

Problem: Students currently only have access to the official train timetable. They have no way of knowing how punctual a specific train connection typically is at a given time of day, which makes it hard to plan connections or decide whether to catch an earlier train to arrive on time.

Use case: For a selected train line and a given timeslot, the system provides the average historical delay for any origin-destination pair along that line. This allows students to plan ahead.

Scope: This project focuses on a selected set of train lines relevant to connections to and from Rotkreuz (e.g. the S1 and IR75). The final line selection is still open, but the approach is not specific to these lines and could be extended to other routes.

Data product: A queryable table providing, for each line, origin-destination pair, and one-hour time slot, the average delay based on historical actual-vs-scheduled data.
